Android app auto update disable

App updates bring new functionality, but they can also break down old features or introduce changes nobody wants. Unfortunately, if you hold a longer version of the app because you don't want to receive updates, it gets harder to keep your app up to date. Sure, you can open the App's Play Store page and disable Automatic Updates settings, but this has side effects. If you've ever gone to the My Apps section of The Play Store and press All Updates, you'll be asked if you want to update the application in question, where it's easy to make the wrong choice. You'll also always see that you have updates available in the My Apps section. The other option is to disable automatic updates altogether, but then you should always check for updates for all your other apps, and you still need to avoid the Update All button. In the past, the only permanent solution to this problem involved using root or modifying APK files on your computer, but both are not an option for everyone. With the method outlined below, you'll be able to stop automatic updates once and for all, and you can do it all from the comfort of your phone. This method should work to prevent any user-installed applications from being updated on the Play Store, but it won't work for pre-installed apps unless you're rooted in. The gist is you'll be side-by-side the version of the app you signed yourself. Since Android won't install different applications signed on top of the rest (although everything is the same), this means you need to uninstall the official version of the application before you sign it yourself and reinstall it to avoid updates. Therefore, the only way to avoid updates to installed system applications is to remove the official version. You can only do so if you are rooted (but if you are, it is only one thing that deletes APK files from /system/application/ or /system/priv-app). However, if you do this for the apps you install yourself, no roots are required. The first thing you need to do is get the actual version of the app you want to keep forever. If you've avoided the updates and versions in question have been installed, you can switch to Step 2. If you've updated it, you'll need to start by uninstalling an updated version of the app, of course. From there, install the version you want to save. The best way to find the older version is to find an application at APKMirror, then an older APK sideload. To do this all on your phone, you only need two apps. The first called APK and you will use it to pull in a copy of the version of the application you want to continue installing. The second application is called Apk Signer Original, and you will use it to prevent the application from being kneaded now. To get both of these apps, search for them by name on the Play Store. Or if you are reading this on your phone, just type each of the following link: Next, open APK Extractor. From the main screen, set it down and select the app you want to move from being kneaded now. Now, may be prompted to grant app storage access, so tap Allow on pop-ups. Then, select the app you want to prevent from being reviewed now (another time) and the app will extract its APK files. At this point, you can unassemble the APK Extraction if you want — the task is done. Next, open the APK Signer app and tap Opt-In/Out. From there, open the ExtractedApks folder, then select the app you unplug in Step 3. With the APK now queuing up, let all the selected options like them, then tap Signature files towards the bottom of the screen. The process of signing files can take up to a minute, but when it's done, you'll be done with the APK Signals app. Next, you need to unassemble the version of the app you've installed right now. This version is signed with the developer's official signature, so a custom signed version of you will not be installed on the existing application. Uninstall by pressing the old app icon and selecting Uninstall, or by dropping it at the Remove installation option at the top of your home screen after pressing long. Next, use any file browser application to navigate to the ExtractedApks folder on your internal storage compartment. You'll see two APKs here — one is the original you extracted in Step 3, and the other is the version you registered in Step 4. The names will be very similar, so to make sure you install the right one, long press and select Rename. Verify that the APK filename ends with the word signed. Otherwise, check other APK. When you are sure you have found a signed APK, make sure you have enabled Unknown Resources. From there, simply tap the file to open it, and you'll be prompted to install your specially signed version of the app. Finally, go to the My Apps section of your Play Store app. If everything comes off without a hitch, you'll see that no updates are available — even if you've had a longer version of the app installed. From now on, you can tap the Update All button when you want, but your modified APK won't be updated. You can also enable automatic updates if you want! This works because of the different signatures you use on APK in Step 4. Signatures are security measures used by Android to ensure that malicious developers cannot impersonate other applications. If the signature two APK does not match, although everything is the same, Android will refuse to install the update. The only way to install updates to existing applications is if the signature matches the original signature, but the corresponding signature can only be created by the original developer. Therefore, by signing an APK with your own custom signature, has basically tricked the Play Store into thinking you don't have the right app installed anymore, thus stopping the pack now.
